

God Tower Game Brief

Unity Android prototype

Version 1.0 | 26 September 2026

Build a portrait climbing game in which a martial arts character scales a towering column, gains height through helpful effects, and recovers from spectacular attacks. The prototype must reproduce the reference video's visual style and climbing feel across five complete levels, including a boxing-glove event triggered by an external request.

Design status. Required items come from the technical test. Observed details come from the video. Proposed rules are implementation choices for this prototype and should be recorded in the project README.

Game at a glance

Attribute	Direction
Genre and format	2D or 2.5D arcade climbing game; portrait presentation observed in the video.
Platform and engine	Android APK built with Unity; recent LTS version, with 2021 LTS or newer recommended by the test.
Player experience	Steady upward progress interrupted by exaggerated boosts, impacts, and recoveries.
Prototype scope	Exactly five playable levels, complete menu flow, character states, and one required external event.

Core game loop

Select a level, begin climbing, and track height on the vertical progress meter. Encounter helpful effects and hazards, recover from hits, and continue toward the summit. Finish the level to advance, or retry after a loss. The video shows a meter with a 5,000 target; using that target for the final level is a proposed choice.

Proposed controls and outcomes

Hold an on-screen **Climb** button to ascend and release it to stay attached in an idle pose. Use Space for the same action in the Unity Editor. A hit temporarily overrides climbing; control returns when the reaction ends. Provide Pause, Resume, and Retry.

Win by reaching the level's summit trigger. Lose if a normal hazard causes a fall below the base after leaving the safe starting area. The required boxing-glove event is nonlethal and must always return the character to playable climbing. These controls and outcome rules are proposed.

Events and upgrade mechanics

The reference combines normal climbing with large effects that change the pace of the ascent. Gift-style notifications are visible, but the required integration is a local HTTP event. A connection to a livestream platform is outside the required prototype scope.

Effects for the prototype

Effect	Evidence and proposed behavior
Boxing gloves	Required. Trigger at least 4-6 animated gloves striking the climber, with a prominent effect across the screen. Proposed gameplay response: a short stagger and a small, nonlethal loss of height.
Jetpack or phoenix	Observed references. The video includes a jetpack event label and a phoenix effect. Proposed behavior: a brief ascent boost followed by normal climbing. Exact strength and duration need tuning.
Axes and explosive attacks	Observed visuals. Flying axes, vehicles, and explosions appear. Proposed behavior: a readable warning, an impact, and a controlled setback. They are additional effects, not individually mandated features.
Event notifications	Observed UI. Short notifications identify events. Proposed behavior: show the effect name and brief feedback without covering the progress meter.

Required boxing glove sequence

While a level is running, either GET or POST to **<http://localhost:56789/bump>** must immediately start the glove effect. Animate at least 4-6 gloves from multiple directions, add impact flashes, screen shake, and a short punch sound, then restore normal play. The event must not crash the game or leave the character unable to move.

Proposed handling for repeated requests: acknowledge each request, restart the visible burst, and cap active effects so the screen and character can recover. Suspend hit penalties during the recovery window. Clear remaining effects when restarting or leaving a level.

Temporary boosts and permanent upgrades

Prototype direction. Treat boosts as temporary effects that expire and reset on retry. Use a fixed duration or upward impulse, with a visible start and end. Repeated boosts may refresh their duration up to a cap; they should not multiply climbing speed without a limit.

Optional future system. Permanent upgrades could improve climbing speed, reduce knockback, or extend boost duration. A simple future loop would award points for completed levels and let players spend them between runs. This is a design proposal, not a requirement or a confirmed feature of the reference. Keep it outside the initial test scope.

Level plan and presentation

The test requires five distinct levels with clear completion conditions and visible progression. The following level names, themes, and encounter patterns are proposed. Keep the basic climbing rules consistent so each new level develops an established skill.

Level	Theme and progression	Encounter focus
1 Tower Base	Clear sky, simple stone patterns, shortest climb.	Introduce the controls and meter. Leave long recovery gaps after light hits.
2 Cloud Rise	More cloud layers and a longer ascent.	Introduce one temporary boost and isolated obstacles.
3 Wind Passage	Cooler sky colors and stronger sense of height.	Alternate hazards and boosts; shorten the gaps modestly.
4 High Tower	Darker stone accents and denser clouds.	Combine familiar attacks in readable sequences. Keep recovery windows.
5 Summit	Bright summit landmark and final platform.	Use the full set of implemented effects. Proposed goal: reach 5,000 height units.

Every level must be completable through ordinary play. Keep all five available in level select for evaluation; save completion marks locally as a proposed convenience. Tune goal height, climb speed, hazard frequency, and knockback together. No numeric balance values are fixed by this brief.

Visual direction and camera

Use a narrow, decorated tower against a blue sky with layered clouds. Preserve the climber's strong silhouette, orange clothing, and readable hand-over-hand motion using appropriately licensed or original assets. The camera follows vertical movement smoothly and may zoom out for large events, as seen in the video. Return to the normal framing after each effect.

Interface and feedback

Provide a main menu, level select, gameplay HUD, pause screen, and win/lose screens. The HUD shows current height, goal height, level identity, and active boost feedback. Keep the vertical meter legible during effects. Win offers Next Level or Level Select; loss offers Retry or Level Select.

Use distinct sounds for climbing, boosts, impacts, victory, and defeat where they support the reference. Keep glove impacts energetic and comedic. Recommended presentation options include sound controls and reduced camera shake; these are additional design choices.

Build scope and acceptance

Technical requirements

Run the local listener inside the game on port **56789**, supporting GET and POST at **/bump** in both the Unity Editor and Android build. Handle incoming requests safely and dispatch GameObject changes to Unity's main thread. A lightweight listener is sufficient. Document the actual device or emulator connection steps and validate them in the final APK.

Recommended implementation: a reusable character controller, a level configuration for each stage, a small event manager, pooled effects, and an explicit state flow for idle, climb, hit, fall, win, and lose. These are implementation recommendations rather than prescribed architecture.

Scope and delivery constraints

The technical test allows 24 hours from confirmed receipt of the reference material. Prioritize climbing feel and camera, the required glove event, five finishable levels, then presentation polish and recording. Source or create all assets independently using free assets with suitable licenses and/or AI-generated art and audio. Paid assets and contributions from an associate artist are excluded; AI coding assistants are allowed.

Completion checklist

- All five levels can be selected, played, completed, and retried in the Android APK.
- Idle, climbing, hit or fall, and win/lose states read clearly; camera and HUD track progress correctly.
- GET and POST requests to **/bump** produce the required glove burst in the Editor and on Android.
- Normal play resumes after the effect. Repeated requests, pause, retry, and scene changes cause no stuck states.
- Art, camera framing, menus, and audio provide a convincing match to the reference; frame rate remains stable on the chosen test device.

Submission package

Deliver an Android APK, a screen recording showing the menu, all five levels completed, and the externally triggered glove event, plus the full Unity project through a single shared entry link. Exclude generated Library, Temp, and Build folders from the source archive. Include a README with the Unity version, assumptions, asset sources and licenses, and tested webhook instructions.

Evaluation weights: visual fidelity 30%, gameplay feel 20%, webhook feature 20%, code quality 15%, asset integration and performance 10%, and delivery and documentation 5%.
